There are a few key differences between the Binomial, Poisson and Hypergeometric Distributions. These distributions are used in data science anywhere there are dichotomous variables (like yes/no, pass/fail). This one picture sums up the major differences.

It is time to see how the three most important discrete distributions, namely the hypergeometric, the binomial and the Poisson distributions work. Let's see a story for each of them. This is in essence the story where we have 30 balls in a box and 12 of them are red.

Its distribution is referred to as a hypergeometric distribution (Weiss 2010). In practice, however, a hypergeometric distribution can usually be approximated by a binomial distribution. The reason is that, if the sample size does not exceed 5% of the population size, there is little difference between sampling with and without replacement (Weiss 2010).

Geometric Distribution & Negative Binomial Distribution The geometric and negative binomial distributions are related to the binomial distribution in that the underlying probability experiment is the same, i.e., independent trials with two possible outcomes.

Mean and Variance. Since a Poisson binomial distributed variable is a sum of n independent Bernoulli distributed variables, its mean and variance will simply be sums of the mean and variance of the n Bernoulli distributions: $\mu = \sum p_i$ and $\sigma^2 = \sum p_i(1-p_i)$. For fixed values of the mean and size (n), the variance is maximal when all success probabilities are equal and we have a binomial distribution.

The key difference between the hypergeometric and the binomial distribution is that the hypergeometric involves the probability of an event when selection is made without replacement. In other words, the hypergeometric setup assumes some dependence amongst the selection of successes and failures.

Hypergeometric Distribution. A hypergeometric random variable is the number of successes that result from a hypergeometric experiment. The probability distribution of a hypergeometric random variable is called a hypergeometric distribution. Given x , N , n , and k , we can compute the hypergeometric probability based on the following formula:

I work through a few probability examples based on some common discrete probability distributions (binomial, Poisson, hypergeometric, geometric — but not necessarily in this order). I assume that you've been previously introduced to these distributions (although this isn't necessary for the geometric problem, as the probability is easily calculated from basic probability rules).

In probability theory and statistics, the Conway–Maxwell–binomial (CMB) distribution is a three parameter discrete probability distribution that generalises the binomial distribution in an analogous manner to the way that the Conway–Maxwell–Poisson distribution generalises the Poisson distribution. The CMB distribution can be used to model both positive and negative association among ...
