Molecular diagnostics is a collection of techniques used to analyse biological markers in the genome and proteome—the individual's genetic code and how their cells express their genes as proteins—by applying molecular biology to medical testing. The technique is used to diagnose and monitor disease, detect risk, and decide which therapies will work best for individual patients.

A genetic test is usually done using a sample of your blood or saliva. If you've been referred for a genetic test because you have cancer, the test will be done on a sample of the tumour that has already been removed as part of your treatment. The sample of blood, saliva or body tissue is sent to a genetic testing laboratory to be analysed.

Molecular genetics is rarely used as a primary test for the diagnosis of an index case whenever a reasonably easy functional test is available. But complementary molecular genetic tests may be useful or even necessary to definitely establish the diagnosis (pseudodeficiencies, instances in which the biochemical test gives doubtful results).

Molecular genetic tests (or gene tests) study single genes or short lengths of DNA to identify variations or mutations that lead to a genetic disorder. Chromosomal genetic tests analyze whole chromosomes or long lengths of DNA to see if there are large genetic changes, such as an extra copy of a chromosome, that cause a genetic condition.
