An optical integrated circuit (IC) is a compactly packaged electronic circuit, chip, or microchip that processes light directly to perform various communication functions. The advantages in using an optical integrated circuit include the higher maximum data speed that can be sent over an optical link as compared to other means and the freedom from damage due to natural and man-made interference and transient energies.

What Is an Optical Integrated Circuit? (with picture)

A photonic integrated circuit or integrated optical circuit is a device that integrates multiple photonic functions and as such is similar to an electronic integrated circuit. The major difference between the two is that a photonic integrated circuit provides functions for information signals imposed on optical wavelengths typically in the visible spectrum or near infrared 850 nm-1650 nm. The most commercially utilized material platform for photonic integrated

Photonic Integrated Circuit (also known as PIC), is a complex integrated circuit which incorporates a lot of optical devices to form a single photonic circuit. The main difference between a PIC and an Electronic IC is that PIC is analogous to an Electronic Integrated Circuit.

Photonic Integrated Circuit Technology

An integrated circuit or monolithic integrated circuit (also referred to as an IC, a chip, or a microchip) is a set of electronic circuits on one small flat piece (or "chip") of semiconductor material that is normally silicon. The integration of large numbers of tiny MOS transistors into a small chip results in circuits
