Turbulence Models and Their Applications. Turbulence models. A turbulence model is a procedure to close the system of mean flow equations. For most engineering applications it is unnecessary to resolve the details of the turbulent fluctuations. Turbulence models allow the calculation of the mean flow without first calculating the full time-dependent flow field.

Turbulence Models and Their Application in Hydraulics. By W. RODI. Inter- The order of the topics in Professor Rodi's title reflects the emphasis of the text; although about a third of this short book deals with example calculations relevant to hydraulics, most of these will also be of interest to workers in other branches of fluid dynamics.

Abstract. Turbulence closures are fundamental for modelling the atmospheric diffusion in numerical codes and the resulting eddy diffusivities are key parameters in describing the transport and dispersion in the boundary layer. In this work, four turbulence closure schemes have been applied for reproducing a neutral flow over schematic complex terrain using the meteorological model RAMS.

LES is much more complex than RANS models, and is better suited for high-end applications (combustion, mixing, external aerodynamics like flow around bluff bodies). Large-eddy simulation (LES) models resolve the largest scales of turbulence and model the rest by use of sub-grid turbulence models or by blending with a RANS model. Positives: Buoyancy

All turbulence models in COMSOL Multiphysics, except the k-? model, support automatic wall treatment. This means that the low Reynolds number models can be used for industrial applications and that their low Reynolds number modeling capability is only invoked when the mesh is fine enough.
